

# Descriptive Crystal Structures

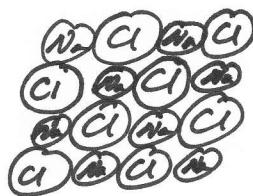

Drawing / visualizing 3-dimensional structures can be very difficult → many 3-d crystal draw-ers / visualizers available online. 2-d representations take some practice and artistic skill.

Symmetry: previously we've worked w/ point groups  
↳ rotational, reflection, inversion etc.  
↳ defined by point, axis, or plane.

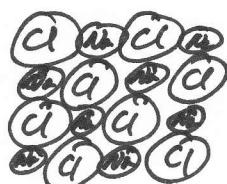

For extended structures (solids, crystals) we are interested in also looking at translational symmetry.

Consider NaCl:

1st layer:

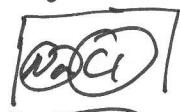

and layer:

3rd layer: same as first.

4th layer: same as 2nd

Identify repeating unit:

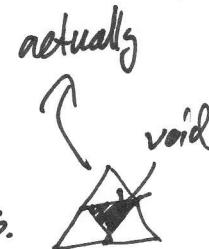

or

we usually pick this one

unit cell: can describe entire crystal structure by just translating by 1 unit cell at a time

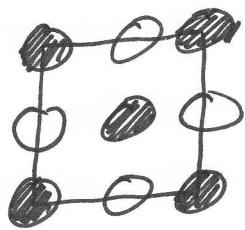

no rotations or other symmetry operations to close pack unit cells.  
(no voids)

vs.

void

In recognition of the unit cell, we can also draw them like this:

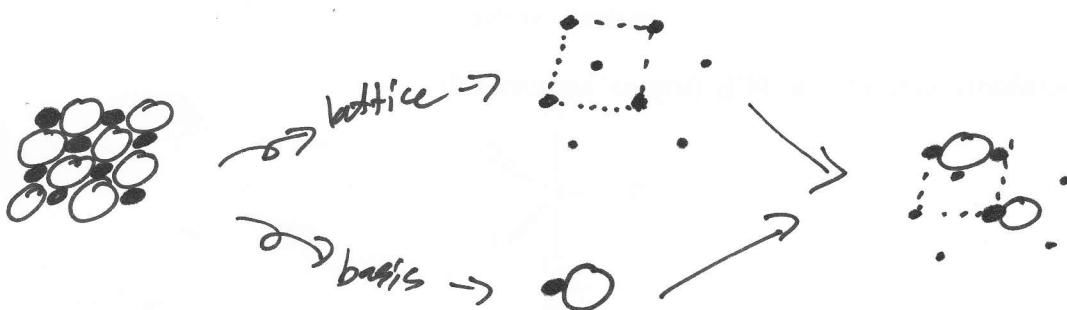

$$\begin{aligned} \bullet &= \text{Na: } 0, 1 \\ &\quad \text{Cl: } \frac{1}{2} \end{aligned} \quad \begin{aligned} \text{specify z height} \\ \text{w/in unit cell length 1.} \end{aligned}$$
$$\begin{aligned} \circ &= \text{Na: } \frac{1}{2} \\ &\quad \text{Cl: } 0, 1 \end{aligned}$$

How to describe this structure more generally to group them w/ other similar structures?

### Lattice and Basis.

$$\begin{aligned} \text{Na: } &\bullet \\ \text{Cl: } &\circ \end{aligned}$$

you can put the basis  
@ any point in the  
lattice to get the  
same structure (i.e.  
all lattice pts. are identical).

→ lattice: FCC  
face-centered cubic

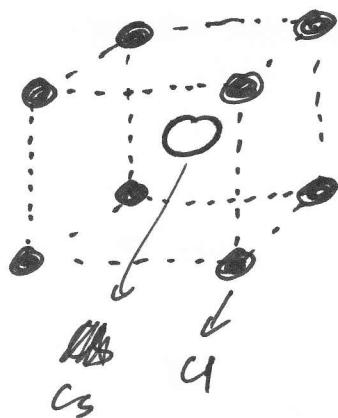

$$\begin{aligned} \text{basis: Na } &(0, 0, 0) \\ &\text{Cl } (\frac{1}{2}, 0, 0) \end{aligned}$$

→ x, y, z w/in unit cell.

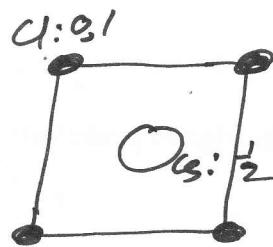

Each unit cell should only contain 1 basis total (for primitive lattices).

→ note: FCC is not a primitive lattice.  
total basis > 1.

Examples: CsCl

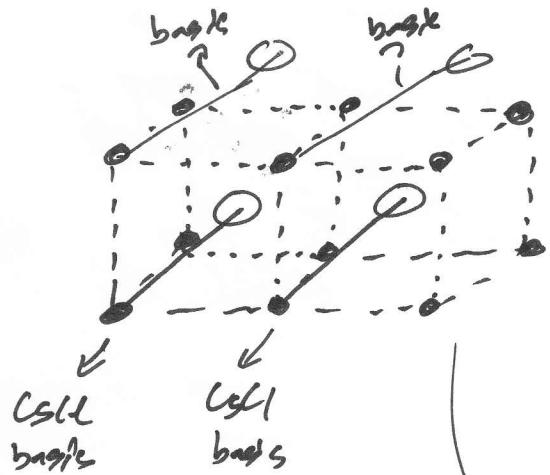

or

What is the lattice and basis? Not bcc!

Simple cubic, basis =  $Cs(\frac{1}{2}, \frac{1}{2}, \frac{1}{2})$  or could also be  $Cl(\frac{1}{2}, \frac{1}{2}, \frac{1}{2})$   
 $Cl(0,0,0)$  for different unit cell drawing.

Simple cubic = primitive cell,  
 1 basis per unit cell.

to take note of edge sharing  
 and vertex/face sharing

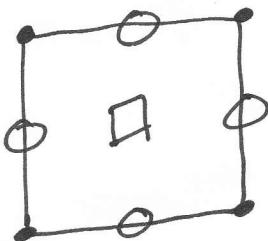

) each vertex shared amongst  
 8 unit cells.

per unit cell:  $8 \times \frac{1}{8} = 1 Cl$

$\downarrow$  vertices       $\overbrace{\hspace{1cm}}$  sharing

$$\frac{+ 1 Cs}{1 CsCl}$$

Example: Perovskites:  $ABX_3$   
 Cation diff. cation anion.

$$O \equiv O: (0,0,0) \quad (\frac{1}{2})$$

$$\bullet \equiv \text{Ba} \quad (0,0,0) \quad (0,1)$$

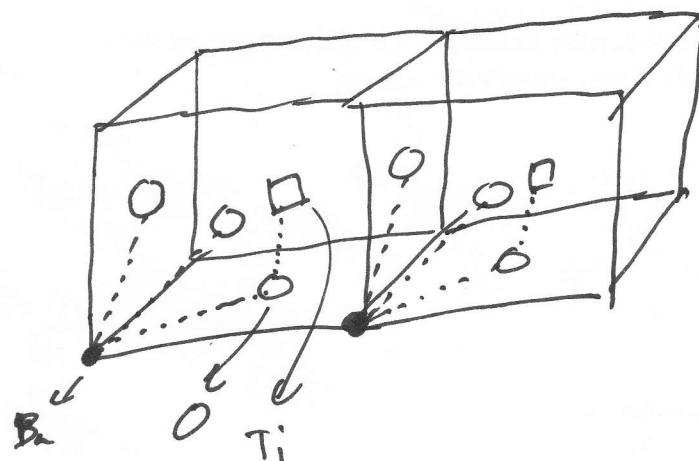

$$\square \equiv \text{Ti} \quad (\frac{1}{2})$$

$$O: (0,1)$$

Ba = vertex

O = face

Ti = body

Simple cubic:  $\text{Ba}(0,0,0)$

$$O(\frac{1}{2}, 0, 0)$$

$$(0, \frac{1}{2}, 0)$$

$$(0, 0, \frac{1}{2})$$

$$\text{Ti} \quad (\frac{1}{2}, \frac{1}{2}, \frac{1}{2})$$

per unit cell:  $\text{BaTiO}_3$ .

Example: Silicon.

Each Si tetrahedrally coordinated.  
 Same structure as diamond.

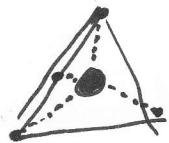

FCC: Basis Si:  $(0,0,0)$   
 $(\frac{1}{4}, \frac{1}{4}, \frac{1}{4})$

Can think of it as one Si FCC lattice +  
 another Si FCC lattice offset by  $(\frac{1}{4}, \frac{1}{4}, \frac{1}{4})$ .

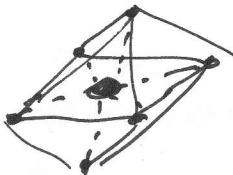

See physical model, or use online 3-d visualizer.

We can also describe these structures based on hole filling.

Generally, two types of holes to fill:

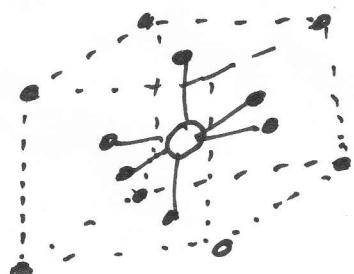

4-coordinate  
tetrahedral

6-coordinate  
octahedral

Na<sup>+</sup>:

FCC Na structure, fill all the octahedral holes.  
w/ Cl.

Si:

FCC Si structure: fill  $\frac{1}{2}$  of tetrahedral  
holes w/ Si.
